Starvation Lake is a small, shallow, highly productive lake located in the Colville National Forest. About twelve people lived around the lake in five homes, several of which appeared to use fertilizers. Varying numbers of cattle grazed in a pasture on the north shore. They occasionally grazed very close to the water. High numbers of both geese and ducks also used the lake as habitat. A wetland surrounded much of the southeastern shore. There were no apparent best management practices in use to prevent watershed activities from impacting the water quality of the lake. The lake lacked buffer zones. A cattle exclusion fence along the inlet stream is needed. High nutrient levels in the lake indicate eutrophy. Some internal nutrient loading probably resulted from apparent hypolimnetic anoxia. Weak or intermittent stratification allowed these nutrients to be periodically cycled into the epilimnion. This resulted in dense plant and algae growth. The macrophyte community was dense, and dominated by one submerged plant, and one floating-leaved plant. The lake experienced tremendous algae blooms for three years prior to sampling, the first of which caused a major summer die off of rainbow trout. Algae decreased toward the end of summer, causing steadily increasing Secchi readings. Total phosphorus concentrations were quite a bit higher than they were during a 1990 survey.

WDFW managed the lake primarily for rainbow trout. About 18,000 were planted each spring. Characteristic of a productive lake, the zooplankton community exhibited a large average size that decreased somewhat toward the end of summer, indicating utilization by planktivores and a possibly ineffective number of piscivores to balance planktivore numbers. Starvation was an extremely popular trout fishing lake with a short take season that lasted from opening day until the end of May. Uses changed to mostly camping and some fly fishing after the first of June. Only two surveys were completed; one respondent also indicated watching wildlife as a primary activity. Many coots, other ducks, turtles, and osprey lived in and around the lake. Questionnaires indicated poor water clarity and aquatic plants as main detractors from the lake, while views, Canada geese, good coldwater fishing, and restricted watercraft were assets.

While surrounding watershed activities clearly impacted the lake, primary uses were largely supported by the eutrophic state of this productive lake. There was evidence of degradation of water quality. Pending a more thorough study, including a nutrient

budget analysis, we recommend a tentative total phosphorus criterion of 90.0 ug/L (mean 68.4 ug/L plus standard deviation of 21.6 ug/L). Future studies will likely recommend lowering this criterion. In the meantime, best management practices should be implemented in the watershed.

Mean Secchi = 3.1m (BN); Mean TP = 68.4 ug/L; Mean Chl = 16.1 ug/L
